System Architecture

The typical architecture involves sensors feeding real-time data into the controller, which processes the information using programmed algorithms?often based on PID (Proportional-Integral-Derivative) control principles?to determine precise adjustments. Commands are then sent to actuators to modulate fuel injection or airflow, maintaining the desired engine speed despite external load fluctuations.

Working Principles of Electronic Governors

Speed Regulation Process

The process begins with the engine running under various loads. Sensors constantly monitor the engine?s RPM and other parameters, transmitting data to the controller. If the engine speed deviates from the set point, the controller calculates the discrepancy and determines the necessary corrective action.

For example, if the engine slows down due to increased load, the controller increases fuel injection through the actuator, restoring the desired speed. Conversely, if the engine speeds up unexpectedly, the system reduces fuel supply accordingly.
